Maxillofacial Radiology

CBCT INCIDENTAL FINDINGS

CASE
Below are two patients that presented to our facility for dental treatment. In both of these patients’ calcifications were noted as incidental findings.

INTERPRETATION
Large field of view cone beam computed tomography (CBCT) images allows the visualisation of anatomical structures outside of the teeth and jaws. These areas include the cranial vault and paranasal sinuses. Occasionally pathology, anatomical variation and various other incidental findings can be seen. As the use of CBCT has become more common amongst general dentists and specialists, awareness and understanding of incidental findings are of great importance, for the patient as well as medico-legal reasons. Calcifications that are found as incidental findings on CBCT scans within the brain can be pathological or physiological in origin. Common
areas within the brain where physiological calcifications can be found include the pineal gland, choroid plexus, habenular, tentorium cerebelli, sagittal sinus, and falx cerebri. The most reported form of physiological brain calcifications is in the pineal gland and is thought to be an age-related change. Pathological calcifications are less common than the physiological variants and are because of more serious diseases such as infectious diseases, endocrine disorders, metastatic lesions, and primary intracranial tumours, to name a few.

Above are images of two patients that presented to our facility for reasons unrelated to the calcifications. The first patient is a 72-year-old female (Images A-C) that presents with physiological calcifications of the falx cerebri. The second patient is an 82-year-old female that presents with physiological calcifications of the choroid plexus glomus (Image D), unilateral globus pallidus calcifications (Image E) and pineal gland calcifications (Image F). Although neither of these patients required medical intervention, a thorough medical history should always be undertaken together with a detailed evaluation of the full CBCT volume, to eliminate possible pathological calcifications.

Dentists and dental specialists should be mindful of incidental findings that may be found on CBCT scans. In cases of uncertainty a dentist trained in maxillofacial radiology and pathology should be consulted as negligence of this nature can result in medico-legal implications.

AUTHORS DECLARATION

Funding: This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.

Conflict of Interest: The authors declare that they have no conflict of interest.

Ethics approval: This study was approved by the University of Pretoria, Faculty of Health Sciences Research Ethics Committee (Reference no.: 478/2021). All procedures followed the ethical standards of the Helsinki Declaration of 1975, as revised in 2008.
